SOCIAL NETWORKS
AS REFLECTION OF ACADEMIC PERFORMANCE

Abstract. Development of media and the Internet leads to the fact that educational establishment stops being the only source of knowledge and information for the school student. A flow of information which is obtained by modern pupils it is so massive that the pupil's ability to select and apply useful information is impossible without the aid of adults. Integration, generalization, the judgment of new knowledge, their coordination with the child life experience from the ability to learn (to teach itself) – here that task, in the decision which school does not have replacement today. The academic progress is that type of pupils' achievements which is often the object of empirical researches. The number of factors which traditionally are considered as predictors of the academic progress of students: the socioeconomic status of the family, self-education time, school environment. According to Colman [Coleman et al., 1966], the social environment of pupils influences their achievements; their environment is also one of the determinants of the academic progress. Scholars describe this effect as the influence of co-education. The growth of classmates achievements affects its educational results. However, even if students were distributed on groups in a casual order, in these groups, they tend to choose to themselves a social environment which will exert a more significant impact on them subsequently, than other members of the accidentally appointed group. The social networks significantly change eventually, especially if it is about networks of first-grade pupils. For example, the pupil can break off the relations with the classmate who receives low marks and to seek to form new communications within the time pupils. The social and economic situation connected with sharp changes in the life of people does relevant problems of harmonious development. Especially problems of success and mental health of children and teenagers in modern society became aggravated.

Keywords: social environment, social networks, internet, academic performance, co-education.

Scientific tools have always played an important role in the scientific progress. The invention of the telescope opened a new vast world of celestial bodies. Observations of the planetary motion laid the foundation of the classical mechanics and gave the rise to physics as a science in the modern sense. The invention of the microscope opened a new vast world of microorganisms and laid the foundation of the modern biology and medicine. Today, we observe comparable changes in the social science. In place of optical instruments are methods of collecting and analyzing digital traces, vast amounts of data made available by the recent development of information technology.

Digital traces allow researchers to see what was previously hidden from them. For instance, educational researchers have long been studying social relationships between students. However, for a long time, the only method for collecting the data on students' social ties was survey. Surveys only allow reconstructing the social network of a small closed group of people. As a result, researchers well understand the social networks of students within one school but know almost nothing about interschool social ties. In contrast, Facebook has information about friendship ties of two billion people. Information about social ties need not necessarily be explicitly indicated, as in the case of friendship on a social networking site. It can effectively be reconstructed from phone calls logs or from information about...
physical proximity from mobile sensors. The direct access to information about human behavior also resolves the problem of censoredness and social acceptability characteristic of survey answers.

Another advantage of digital traces is a significant reduction in the cost of research. The largest international study on education PISA covers about 500,000 students. Its organization requires a large amount of resources and coordinated effort from dozens of teams in different countries. At the national level, studies with several thousand participants are considered as large. The thesis could be successfully completed with hundreds or even dozens of respondents. Data from social networking sites allow individual researchers to work with much larger samples up to tens of millions of participants. Data need not necessarily to be accessible directly. It was previously shown that various socio-demographic characteristics such as ethnicity, gender or income level could be effectively predicted from tweets, profile images, user posts, or photos of neighborhoods.

Traditionally, social sciences make an emphasis on theories and their ability to explain human behavior while ignoring their predictive power which is often much inferior to natural sciences. This significantly limits the possibility of practical application of such knowledge. One of the reasons for the weak predictive power lies in the fact that social systems and the laws that govern them are too complex to be described by simple variables. For instance, a variable with a few discrete values cannot describe the wide variety of personal characteristics and human behavior even in theory. Today, thanks to big data, one could construct new variables with much greater predictive power. For instance, it has been shown that information about the likes on a social networking site allows to predict various personal traits from sexual preferences to intelligence and parents’ divorce. While individual likes do not have much predictive power, together they form a unique digital trace that contains a significant amount of information about an individual.

Thus, the use of digital traces for studying the human behavior is one of the most promising and actively developing areas in the social science. This approach has a great potential in the education science as well. In the Russian context, the most promising source of data is the social networking site VK, that is already been used in educational research. VK is of particular interest not only because it provides an access to a vast amount of data but also because of its role in the lives of modern students.

Today, young people are almost always online and spend most of their online time on SNSs. Recently SNSs have become the main source of traffic to other resources of the Internet. In Russia, the largest SNS VKontakte (VK) is named as the main source of information about the country and the world by 70.3% of young people, more than any other source of information. This SNS is also more trusted by young people than traditional media. Thus, VKontakte largely determines the information environment of modern Russian students. That is why it is particularly important to study the nature of this environment and to understand whether it is different for different groups of students.

This work is devoted to the development of methods for mining and analyzing VK data in the context of educational research. These methods are applied to study differentiation of students by academic performance. The need to develop the methods is due to the fact that little is known about the reliability of the data and the potential biases of VK samples and that analysis of big multidimensional data requires special approaches. The differentiation of students on a social networking site is of particular importance in the context of digital inequality.

**Theoretical framework.** The authors of the concept of digital inequality note that one generalization that emerges from research on inequality in access to information about cultural resources is the differentiation principle. This principle means that at the beginning – when access to a particular resource is limited – the use of this resource remains relatively undifferentiated. When the resource becomes more accessible, its use becomes more differentiated. It is explained by the fact that more-privileged groups find a way to use the resource to extract more from it than less-privileged groups.

The typical example here is education. When access to secondary education became almost universal, most children from the middle and upper classes started to attend universities. At that point, university degrees became the main differentiating characteristic. When higher education became widespread, two groups of universities emerged: mass universities and selective universities, and the main differentiating characteristic shifted from having any higher education degree to graduation from the prestigious university.
The same principle applies to digital resources. In theory, the global network provides all students with equal access to virtually unlimited knowledge. However, as early as the mid-1990s, researchers became concerned about the digital divide between those who have or do not have access to computers (later to the Internet). When the Internet became ubiquitous, the concern was about the second digital gap related to the gap in the level of information literacy and the ability to use all the opportunities that are provided by the Internet. Today, the main focus is shifted to a broader concept of digital inequality, which is understood as the difference in the Internet use (or the use of any other digital technology) between groups of people who have formally equal access to it.

The existing research suggests that there are significant differences in the Internet use between users with different levels of formal education. More educated people often use the Internet for capital-enhancing activities (such as job seeking, seeking for medical or professional advice, and acquiring new knowledge) while lower educated people use it predominantly for entertainment. It was also found that students with low socioeconomic status enroll less often in online courses and if they are enrolled then they successfully complete it less often than their peers.

In most cases, the comparison is made between broad socio-demographic groups (such characteristics as gender, level of education, etc. are analyzed). The information about the use of the Internet is obtained from surveys. In our work, we suggest using much more detailed data namely the information about the academic performance of students and detailed information about their actual behavior on a social networking site. The aim of the study is to develop methods for mining and analyzing VK data and to apply these methods to understand the nature of the relationship between students’ behavior on the SNS and their academic

**Methodology and design of the study.** For the purposes of the study, we developed a software program that performs queries to the VKontakte API and receives a list of all users of a certain age who indicated that they are studying at a given educational organization. The program matches and merges information from user profiles with information about students from the educational organization. After the merge, the data is anonymized and stored for later research.

A direct matching by first and last name allows identifying only a small proportion of the students. That is why we additionally created an extensive dictionary of various forms of the same name (for example, Ivan-Vanya-Vanyusha), and also developed an algorithm for matching names that are written in Latin and Cyrillic. The program searches not only among users who indicated that they are studying in a given educational organization but also among their friends on the social network.

In the case when information about students was not available, we excluded from the sample those users who did not have friends from their own educational organization. This approach allows one to efficiently filter out profiles with inaccurate information.

We use this method to collect four unique data sets that combine educational data with data on the online behavior of students.

The latest sample includes participants of a longitudinal panel study “Trajectories in education and career” who agreed to provide their personal information for research purposes.

To study the relationship between the structure of friendship ties and the structure of educational organizations, we compute modularity Q for partitions of the entire network corresponding to the partition of a school into grades and buildings and the partition of a university into years of studies, educational programs, and campuses. To ensure that observed values of Q cannot be explained by random noise, we use a permutation test. We fixed the structure of a network and randomly permute the attributes of nodes (i.e. school grades, educational programs, etc.). We then computed Qrand for such a random network. Comparison of 10 000 generated Qrand values with Q allows us to compute the significance level for the observed results. To study the relationship between the structure of friendship ties with geographical distances, we analyze the relationship between the probability of the friendship tie between two schools and the distance between them.

To investigate the detailed evolution of social ties within an educational organization, we use information about the interaction between students instead of information about their friendship ties. We split the period of the study into 3-month intervals and then for each of the intervals we built a network of social ties. We assume that the tie between two users exists if one of them gives at least one “Like” to another on VKontakte during this period. We then compute the Pearson correlation coefficient between
the academic performance of students and the average academic performance of students connected to them. This approach allows us not only to determine the level of differentiation of social ties by academic performance but also to track its evolution with time.

The level of social ties differentiation on a city scale was estimated by computing a correlation coefficient between the average USE scores of graduates of a school and the average USE scores of graduates from schools with which this school is connected on the SNS. Two schools are considered connected on SNSs if there is at least one friendship tie between their students on such sites. To ensure that any observed effect is not driven by geographical locations of schools, we use a random graph model that preserves the relationship between the probability of a friendship tie between schools and geographical distance between them.

We analyze the interests of VKontakte users using information about their subscriptions to various public pages (groups) on the SNS. We compute the average GPA for subscribers to different pages along with their average age and proportion of females among them. To show that there is a correlation between interests and academic performance, we build a model that can predict academic performance from information about subscriptions. We identify the main components containing information about students' interests and then use them in a linear regression model to predict academic performance.

Main results.

</tr>
</tbody>
</table>

Information about friendship ties allows to effectively filter out fake profiles. By one of our estimates, the number of fake profiles could be reduced from 66% to 8% on the “School” sample if users who do not have friends from this school are excluded.

We show that online social ties of students from an educational organization are differentiated by academic performance, namely that students with similar academic performance are interacting more frequently online. We also find that the level of this differentiation increases with time. We show that this increase cannot be explained by changes in academic performance but rather is explained by rewiring of social ties. Less-similar students break social ties with higher probability and more-similar students create new ties with higher probability. These results are presented in.
We also study the social ties of students on a city scale. We show that the probability of a friendship tie on VK between students from different schools is higher for the schools with similar academic performance. These results hold true regardless of the geographical distance between schools. Hence, schools are segregated in the digital space despite the absence of geographical segregation.

**Differentiation of interests in the digital space.** We find that students’ interests are correlated with their gender (for instance, boys prefer public pages related to football and computer games), age (for instance, older students are interested in graduation examinations) and also with their academic performance. Low-performing students are subscribed to such pages as “Love Horoscope” and “Unorthodox Horoscope” while high-performing students prefer such pages as “Interesting facts” and “The best poems of great poets”.

We also show that online interests could explain as much as 25% of the variation in academic performance of students. This is comparable to the percentage of variation that can be explained by the socioeconomic status of students. The gap in educational outcomes of subscribers to different groups (for instance “World Art and Culture” and “Love Horoscope”) could be equivalent to two years of formal schooling (table 4).

**Table 4** – Names of public pages that contribute most to the academic component of users’ interests. Names are translated from Russian. Mean values of subscribers’ scores with standard errors (in parentheses) are provided for each of three PISA subjects.

| Cool Gags                | 467 (4.9)  | 444 (5.1) | 465 (4.9) |
| Unorthodox Horoscope     | 462 (5.1)  | 450 (5.3) | 460 (5.0) |
| Love Horoscope           | 450 (5.3)  | 442 (5.8) | 453 (5.2) |

These results could be summarized as the following:

– the method we propose allows to extract reliable information from VK and to combine it with educational data; resulting data could be used to study social ties of students and their interests;

– the structure of online friendship reproduces the structure of educational organizations; the social proximity in the digital space is closely related to the geographical proximity; the probability of a friendship tie between students from different schools declines with geographical distance following power law;

– social ties of students are differentiated by academic performance in the digital space; students with similar performance create ties with higher probability and students with dissimilar performance break ties with higher probability; the students from similar performing schools are more often connected on a social networking site regardless the geographical distance between schools;

– students’ interests are differentiated by academic performance in the digital space; the gap in educational outcomes of subscribers to different public pages could be equivalent to two years of formal schooling.

**Conclusion.** For the purposes of this work, we use only publicly available information from the social networking site. The VK team confirmed to us that this data can be used for research purposes. The matching of VK profiles with information about students was done automatically, after matching the data was anonymized and later used for analysis only in this anonymized form.
It is important to note that new sources of data not only open up new opportunities for researchers but also raise new ethical questions. For instance, the notion of informed consent requires special attention. By accepting terms of service users of social networking sites agree that information about them could be accessed by third parties and used for a variety of unspecified purposes. However, it is not clear if such consent could be considered as informed. Especially considering the fact that terms of services are rarely read and if read then users may still not fully understand all the consequences of their consent. For example, it was shown that digital traces allows to effectively predict information that users did not disclose and may prefer not to be known by others. Despite the appearance of the first ethical guidelines this field is still largely a grey zone and requires additional attention from the research community.

We have conducted the first large-scale study that combines detailed information about the behavior of students on VK with educational data. We introduced methods that could increase the reliability of VK data and provided estimates for sample biases. We introduced a novel approach to studying the evolution of students’ social ties that did not require to conduct expensive longitudinal studies. We showed how publicly available information from SNSs could be used to infer information about students’ interests and that this information could have a large predictive power in respect to various students’ characteristics including their age, gender, and academic performance. These results are important for further educational research because our methods could be adopted by other researchers and have already been used in various works.

For the first time, the structure of students’ friendship ties have been studied on a city scale and the relationship between inter-school friendship and geographical distance has been revealed. We also studied the evolution of social ties of students within educational institutions and showed that the differentiation of these ties by academic performance increased with time. We explained the mechanisms behind this phenomenon with a simple model. We showed that there was a differentiation of students’ online interests by academic performance and, for the first time, provided an estimate of the gap in educational outcomes between subscribers to various public pages.

We showed that social ties of students and their online interests had a large predictive power in respect to academic performance. The variables that were constructed by us explained as much variation in educational outcomes (for individual students and for whole schools as well) as the socioeconomic status measured by traditional indexes such as the index of economic social and cultural status (ESCS) used by PISA. This allows one to use constructed variables for operationalization of social and cultural capital of students (at least for its digital dimension). Traditional indexes include such variables as parents’ level of education and number of books at home. Such variables have a low resolution (e.g. parents’ level of education) or disputable face validity in the modern world (e.g. a number of books at home). Another advantage of our approach is that it shifts focus from family characteristics to characteristics of students themselves.

It is important to note that our results do not give an answer to the question of whether the observed differentiation leads to amplification or reproduction of inequality. We also do not study any effects that families might have on the observed differentiation. Further research might seek answers to these important questions.

Our results may have implications for the practice of education due to the important role that SNSs play in the life of modern students. The main component of the SNS is a newsfeed that is constructed from information posted by friends and from subscriptions to various public pages. We showed that both of these sources are differentiated by academic performance. It means that everyday digital flow of information is fundamentally different for students with varying academic performance. This fact should be taken into account by teachers in their everyday practice. The digital environment of students is out of the control of traditional pedagogical tools; however, teachers could influence it. For instance, one of the main features of modern SNSs is recommendation algorithms that suggest new information based on the history of users’ behavior. Our research showed that this might lead to information bubbles of horoscopes and cool gags for low-performing students. Teachers, however, might ask their students to find some educational information on SNSs or elsewhere on the Internet. This student activity will lead to digital traces that later could be used by recommendation algorithms to show students new information that might be more enriching than information that would be shown without intervention. Development of similar pedagogical interventions along with studying of their potential impact may be a logical continuation of our work.

ЭЛЕУМЕТТІК ЭКОНОМИКА – АКАДЕМИЯЛЫҚ БІЛІМ БЕРУДІҢ ДАМАУЫҢЫҢ НЕТГІЗГІ ФАКТОРЫ

Аннотация. Χылқының өмірінің тұбесінің өзгертілі ұлғым мен техникалық қарқынының дамуы, қанда қапаррттық технологиялардың пайда болуы адамдарға қанықтың үйіріздігі және ізгеруді, біліктілігі артықсыз, қанда мамандықтардың қанықтығы әрқайсы болуы мүмкін. Қазақстандағы тұлғалардың алымын қапар қарым-қатынас қор, оның қанықты үйірізді құлдарға қадағалуды мүмкіндігі ерек-секторларға қорнайды.

Жана білімді интеграциялау, ұлғымдау, менгеру балалының оқу қабілетінің қалпықсатасуы (өзін-өзі өкіту) негізінде өмірілік тәжірибесімен байланыстырған бір түрі. Мүлінекет ешқандай алмайтын өмірілік суроқтару өкітовдың құралы. Қазақстандағы балалының білім беру өтетін жасының қарары, қандақтың, және құлдағы қарым-қатынас қор, оның құмдылығын қорнайды.

Түінің сөзі: элеуметтік, философия, интернет, академиялық, үлгерім, бірлесе өкіту.
тому, что образовательное учреждение перестает быть единственным источником знаний и информации для школьника. Поток информации, который получают современные учащиеся настолько огромен, что умение ориентироваться в ее отборе и применение в своей деятельности невозможно без помощи взрослых. Интеграция, обобщение, осмысление новых знаний, увязывание их с жизненным опытом ребенка на основе формирования умения учиться (учить себя) – вот та задача, в решении которой школе сегодня земля нет. Начальное образование – это фундамент всего дальнейшего общего и любого профессионального образования. Успешность обучения в начальной школе во многом определяет судьбу человека, его будущую жизнь, поскольку именно в том возрасте, в котором обычно проводится начальное образование, формируются базовые основания личности человека. В многочисленных эмпирических исследованиях было показано, что социальное окружение учащихся влияет на их академические результаты, причем влияние наиболее успешных сверстников гораздо сильнее. Опыт межличностных отношений с другими людьми, взрослыми или сверстниками, является фундаментом для развития личности ребенка, становления его самосознания. Младший школьный возраст наименее изучен с этой точки зрения и остается открытым периодом в генетической линии развития межличностных отношений. Поскольку ведущей в этом возрасте традиционно считается учебная деятельность, то исследования, касающиеся данного возрастного периода, были направлены преимущественно на изучение психологических способностей, связанных с ней: познавательных способностей ребенка, компонентов учебной деятельности, рефлексии и т.п. Но, помимо общения на уроке, младшие школьники вступают в достаточно сложные межличностные отношения между собой, и психологические особенности этих отношений останутся менее изученным. Социальные сети являются новой площадкой общения детей, и здесь особую актуальность приобретает то с кем и как дети общаются.

Ключевые слова: социальная среда, социальные сети, интернет, академическая успеваемость, сообучение.
